Preliminary Data Report for Stormwater Runoff Samples Collected in DP Canyon above Los Alamos Canyon at Gage E040 on October 12, 2000

A precipitation event occurred over the Jemez Mountains and the Pajarito Plateau on the afternoon and evening of October 11, 2000 and during the early morning hours of October 12. On October 12 meteorological stations across the plateau recorded a range of precipitation from 0.25 to 0.58 inches for the day. The station at TA-6 recorded a total of 0.47 inches and the station at TA-53 recorded a total of 0.49 inches. Remote Automated Weather Stations (RAWS) located on US Forest Service land in the Jemez Mountains recorded 0.28 inches in Pueblo Canyon, 0.49 inches in upper Los Alamos Canyon and 0.40 inches in Pajarito Canyon. Figure 1 shows the pattern of precipitation that was recorded in the Jemez Mountains and on the Pajarito Plateau on October 12.

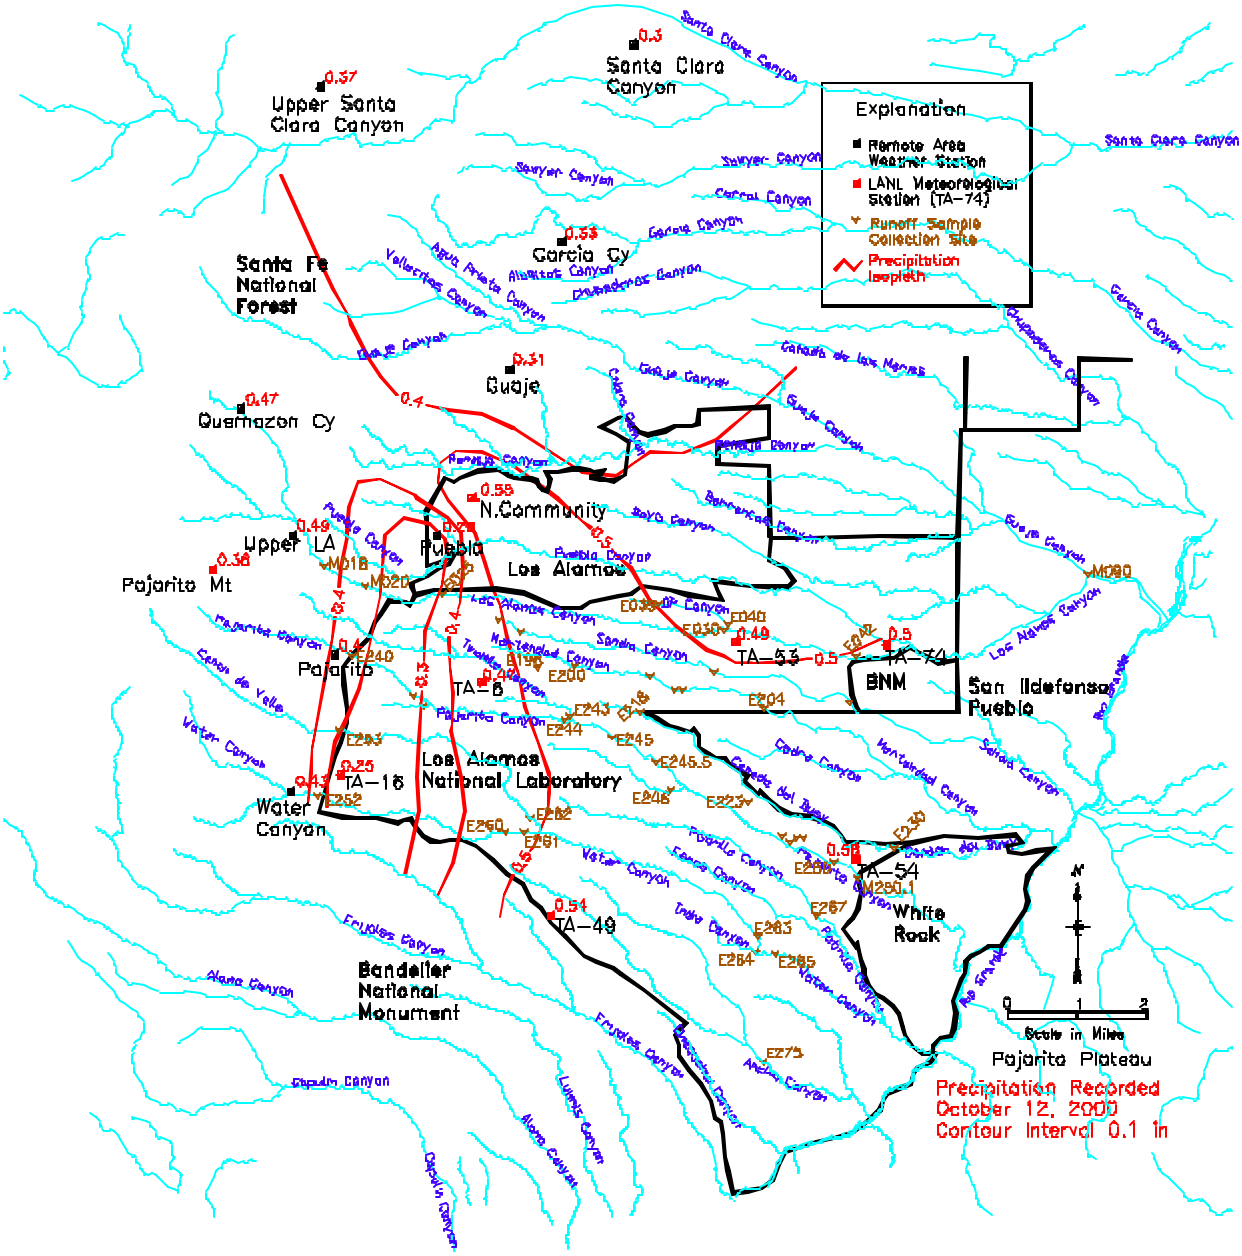

Figure 1. Precipitation recorded at meteorological stations on the Pajarito Plateau on October 12, 2000

During the precipitation event, stormwater runoff samples were collected in DP Canyon above Los Alamos Canyon at gaging station E040. Automated samples were collected at 05:48 hours during the morning of October 12. Figure 2 shows the hourly precipitation recorded at the TA-6 and the TA-53 meteorological stations on October 11 and 12, 2000.

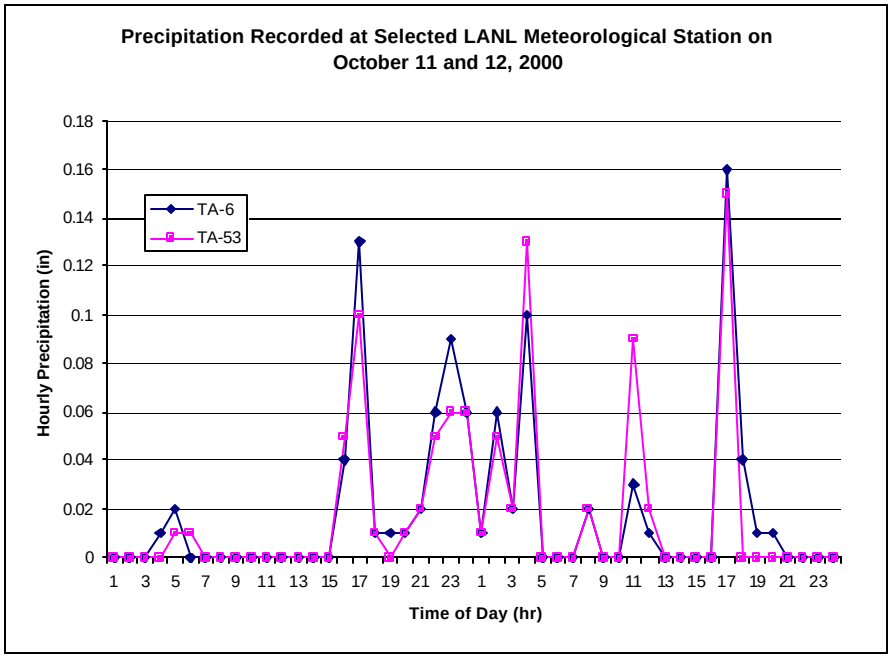

Figure 2. Precipitation recorded at TA-6 and TA-53 Meteorological Stations on October 11 and 12, 2000.

Unfiltered samples were collected for analysis. The samples were sent to General Engineering Laboratories, Inc. in Charleston, South Carolina for analysis for radionuclides and general inorganic constituents. The second sample collected at 05:48 remained unfiltered for the analysis of total suspended sediment (TSS). Filtered samples were not collected.

Preliminary results of the available analyses for radionuclides are shown in Table 1. Also shown on Table 1 are the maximum values of constituents that have been recorded previous to the Cerro Grande Fire in unfiltered stormwater runoff at LANL (1995 through 1999), the DOE Public Dose Derived Concentration Guides (DCGs), and the available Environmental Restoration Project's Ecological Screening Level (ESL) for water; these values are presented for comparison purposes. Results of gamma spectroscopy are reported only for Am-241, Cs-137, and other radionuclides that were detected in concentrations above the laboratory method detection limit. A summary of the preliminary results of the analyses is shown in Figure 3. The results are compared with the historic maximum values obtained for unfiltered runoff and the DOE DCGs and the ESLs.

The radionuclide results obtained to date for the unfiltered samples collected from DP Canyon at E040 on October 12 are below the historic pre-fire maximum values and the DOE DCG and ESL values for each analyte result obtained to date.

The unfiltered runoff sample collected at E040 on October 12, 2000 at 05:48 contained 3150 mg/L total suspended solids (TSS). Based on this sediment concentration and the activity of radionuclides measured in the unfiltered water samples, the concentrations of the radionuclides in the suspended sediment fraction of the runoff samples were calculated. These calculated values are also shown on

Table 1 and the data are summarized in Figure 4. Values for radionuclides that were reported below the method detection limits are not shown on Figure 4.

The background values (BVs) that have been determined for stream sediments at Los Alamos National Laboratory (Ryti et al. 1998) and the calculated residential screening level (RSL) or soil for each radionuclide are also shown on Table 1. The RSL values were derived using DOE's RESRAD code and are based on a dose limit of 10 mrem/yr, which is less than the DOE free-release dose limit of 15 mrem/yr (LANL 2000). The maximum value of radionuclide concentrations observed in ash and muck sediment samples collected in June after precipitation events by the LANL ER Project are also shown on Table 1 (LANL 2000). The BVs for stream sediments, the RSLs, and the maximum ash and muck values are provided as a comparison for the results of the calculated activities of radionuclides in the suspended sediment fraction of the runoff samples. Suspended sediments in runoff samples are typically finer-grained than stream sediment samples; some radionuclides have been found to be preferentially located in finer grained sediments so direct comparison of the suspended sediment fraction of runoff samples with stream sediment BVs may not be appropriate, however the BVs, RSLs, and maximum values of ash and muck samples are provided here for reference and comparison.

The calculated radionuclide concentrations in the suspended sediment fraction of the samples are above the stream sediment BVs for Cs-137, Gross Beta, and Sr-90. The calculated concentration of Sr-90 is also above the RSL and the ER ash and muck maximum values.
